

MU-MatriX

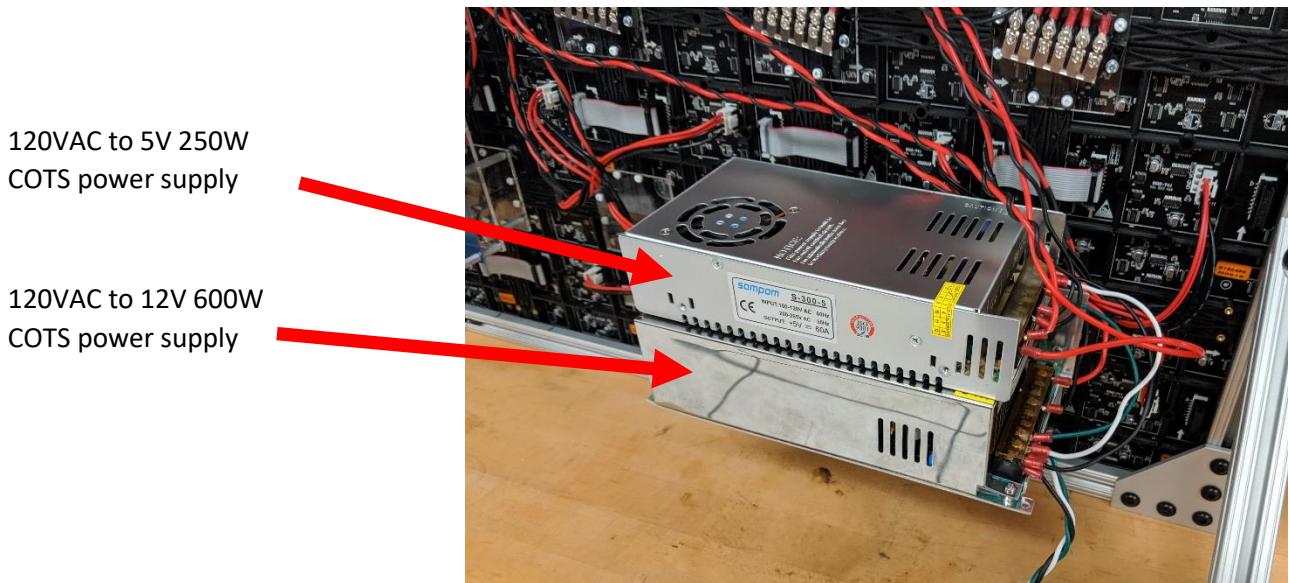

Repair Guide

Caroline Gilger, Logan Wedel, Drew Maatman, Kevin Etta, Tuoxuan Ren

Power Distribution Wiring:

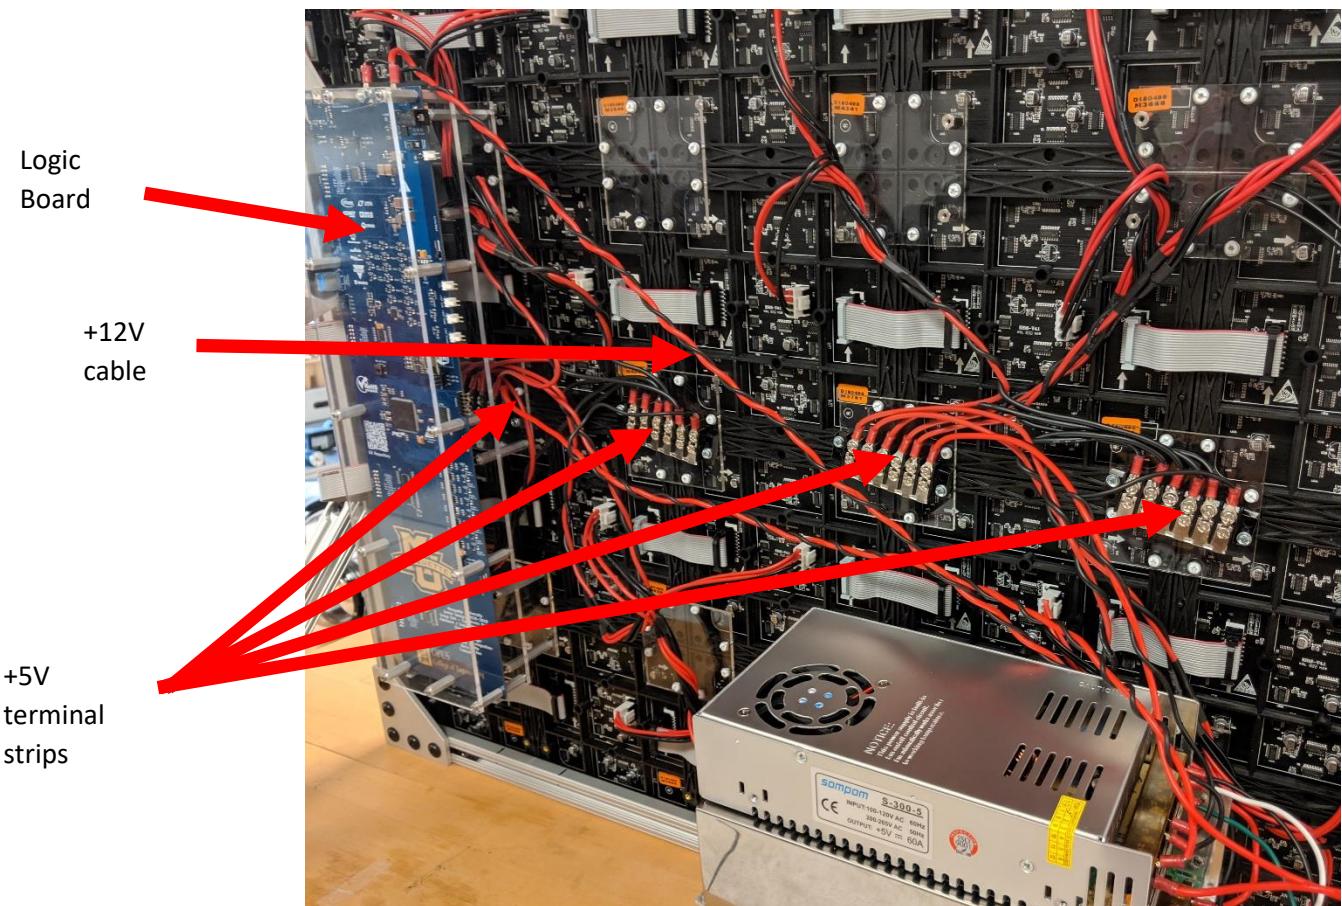

The power tree above graphically describes the different voltages used in the device. A single wall voltage inlet powers both the COTS 120VAC to 12V and COTS 120VAC to 5V chassis power supplies. The 120VAC input voltage is wired using black, white and green wires for live, neutral and earth connections. The wired connections are insulated with hot glue at the input terminals for the COTS converters. This was done to protect a user from touching high voltage connections with their fingers. The COTS power supplies are shown below:

Each COTS power supply has various pairs of output wires running from the output terminals of the converters to the respective load terminals. The 12V COTS converter only powers the logic board.

The 12V COTS converter is dramatically oversized and over rated for this application, since the project originally had a different power configuration. If the 12V COTS power supply fails, it can be replaced with a much smaller power supply. The 5V COTS converter attached above it, however, needs to be at a 250W power rating, or more. Replacing the installed converter with a higher output power rated converter could be beneficial in the future, but 250W seems to be great right now. The 12V COTS power supply is mechanically attached to the project using #4-40 screws and standoffs, which attach the frame of the power supply to the acrylic brackets which hold the corners of the LED panels together. The 5V COTS power supply is attached mechanically to the top of the 12V COTS power supply using poster mounting putty. At the time, this seemed like a strong enough solution.

The output terminals of the 5V COTS converter is wired to four 6-circuit terminal strips, two of which distribute the 5V output wires to all of the LED panels, and the other two terminal strips which distribute the ground connections to all of the LED panels. The 5V terminal strips have all red wires leading into and out of them, while the ground terminal strips have all black wires leading into and out of them. All red and black wires that distribute 5V connections, 12V connections, and ground connections are terminated with red ring terminals, which allow the wire connections to be screwed into the terminal strips and onto the blue logic board which controls the project. All power distribution wiring is 14 gauge wire. Only use this gauge wire or thicker for minimum resistivity of electrical connections. This is especially critical for the 5V connections. The output wiring of the COTS power supplies is shown below:

Wires are connected to the terminal strips and COTS power supplies using phillips screws. Wires are connected to the blue logic board using Metric 4 nuts. Wires are connected to the LED panels using

the LED panel connectors, which are available on ebay, amazon, and Alibaba (HUB75 LED Panel Power Cable). The connector housing and power cable for the LED panels are included in one wiring harness assembly when purchased online.

Logic Board Hardware Repair:

Logic board components should not fail, but if they do, the most likely components to fail are the ceramic capacitors, which will most likely fail short. Most passive components on the logic board are 0603 case size, 1% resistor tolerance, 1/10W resistor power rating, 50V capacitor voltage rating, X7R capacitor dielectric. The logic board hardware schematic included as an appendix shows components parameters for most components, and if parameters for certain components are not shown, assume these parts have the parameters listed above. The hardware schematic is included as an appendix in PDF form, as well as a bill of materials, but the actual design files can be accessed from the project Git repository at https://github.com/drewsum/Electronic_Display. Contact Drew Maatman at drewmaatman@gmail.com if these files cannot be accessed. All hardware design files are opened with KiCad 5.1.0, and are located within the project repo in hdw/Logic_Board/LED_Display_Controller. Custom schematic symbols and PCB footprint libraries must be added to the KiCad path to be able to open the schematics and PCB layouts. These libraries are located in the project Git repo at hdw/lib.

Only integrated circuits on the logic board have their reference designators printed in PCB silkscreen (parts with Uxxxx reference designators). This is done to keep more space on the PCB to allow parts to be placed more densely, since so much circuitry had to be crammed onto the board. In order to locate a particular component on the circuit board using a component reference designator from either the schematic or bill of materials, use the KiCad PCB editor and the find tool (Ctrl+F) to search for that component by reference designator on the PCB. KiCad will highlight this component on the PCB, which allows someone to locate the component on the physical hardware. PCB footprints within the KiCad board layout can be clicked to see what the reference designator of the component is, as well as value. This accomplishes the opposite of finding a part by reference designator with Ctrl+F. When a component is selected in the PCB layout in KiCad, the schematic symbol will be pointed to in the KiCad schematic, and vice versa.

The logic board is powered by 12V cables from the 120VAC to 12V COTS power supply, described above. Output data from the logic board is transferred into the LED panels (and across LED panels in a serial fashion) with 16 circuit IDC connectors and ribbon cables. These are the grey cables running across the LED panels and from the logic board into the LED panels. These ribbon cables and IDC connectors can be removed, and they can only be installed in the correct way, since the connectors are keyed.

Logic Board Mechanical Installation:

The logic board has acrylic cover plates on both the top and bottom. These protect the logic board from being damaged. Both acrylic covers are attached to the logic board with #4-40 machine screws and standoffs. These screw into four mounting holes that span the perimeter of the logic board. The lower acrylic protective plate has other holes drilled into it to allow mounting to the acrylic panel corner brackets, which fix the logic board into position on the back of the LED panels. The machine screws and taller standoffs which attach the logic board to the corner brackets are also #4-40. Varias washers protect the acrylic from too much direct clamping force. These standoff connections are shown below:

Shorter standoffs
which connect
lower acrylic
protective plate to
logic board

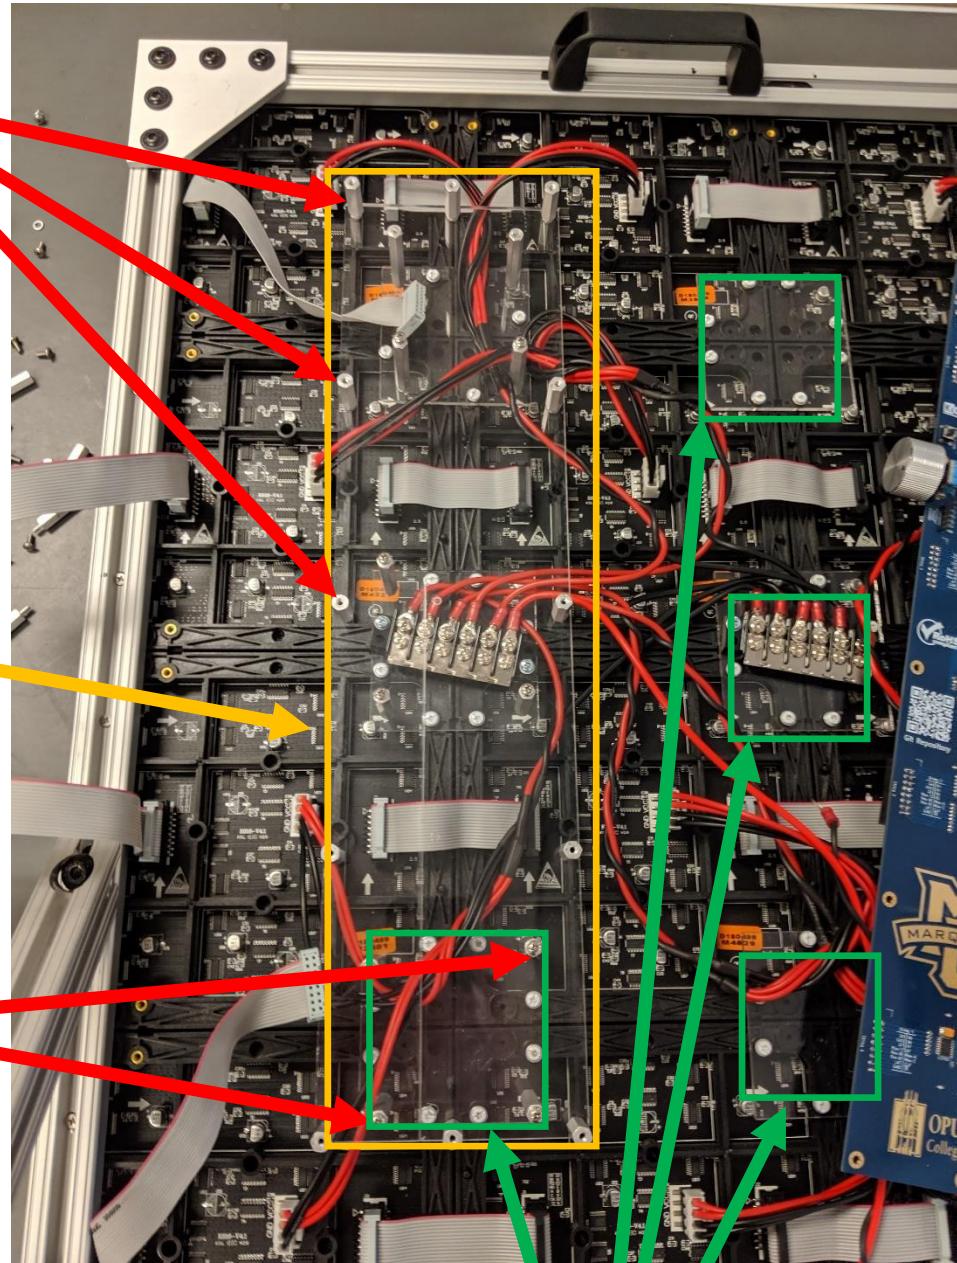

#4-40 fasteners

Lower acrylic protective
plate (Custom laser cut
acrylic)

#4-40 fasteners

Taller standoff
connections
which mount
lower protective
plate to corner
brackets

#4-40 fasteners

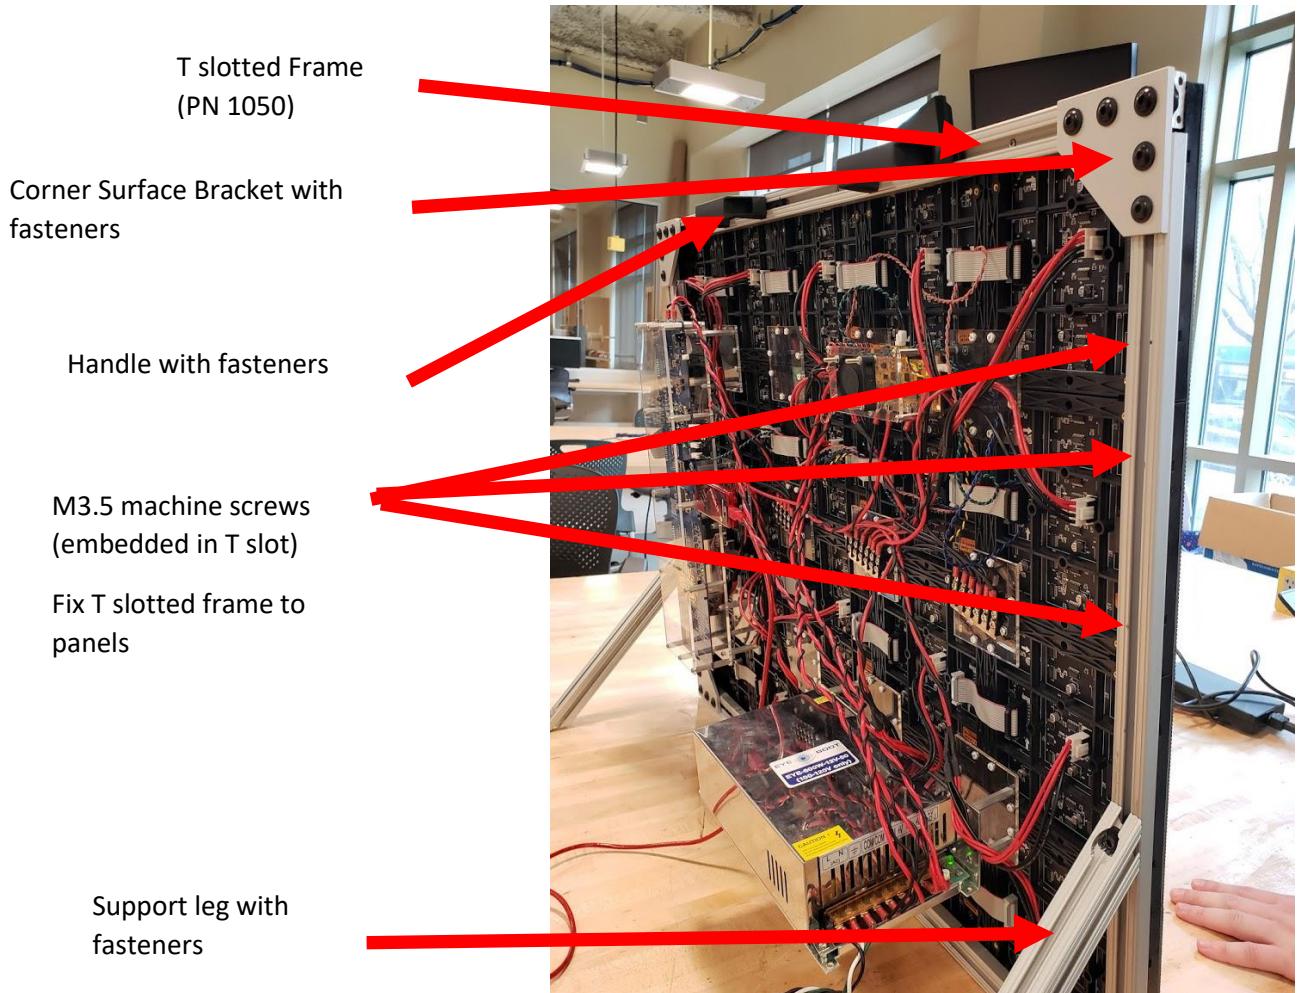

Corner brackets (Custom
laser cut acrylic)

M3.5 fasteners

T-slotted Frame:

The entire project is held together with extruded aluminum T-slotted framing. The exact 80/20 part number used is 1050. The T slotted framing is 1" wide by 0.5" tall, and two bars of 3 foot lengths were cut to custom lengths to run the perimeter of the display. The T slotted framing is fixed to the LED panels using counterbore metric 3.5 phillips machine screws. These screw through T slotted framing into brass inserts in the LED panels. The four corners of the frame are held together with corner surface brackets, available from McMaster-Carr with PN 47065T267. The included fasteners are used to fix the corner brackets into the T slotted frame. These fasteners have a torx head, T27 or T30. In addition to the corner surface brackets, handles are included for easy handling on the top bar of the T slotted frame. These are McMaster-Carr PN 47065T164, and also include fasteners. The support legs added to the sides of the T slotted frame are McMaster-Carr PN 47065T186. These also include fasteners. The complete T slotted frame is shown below:

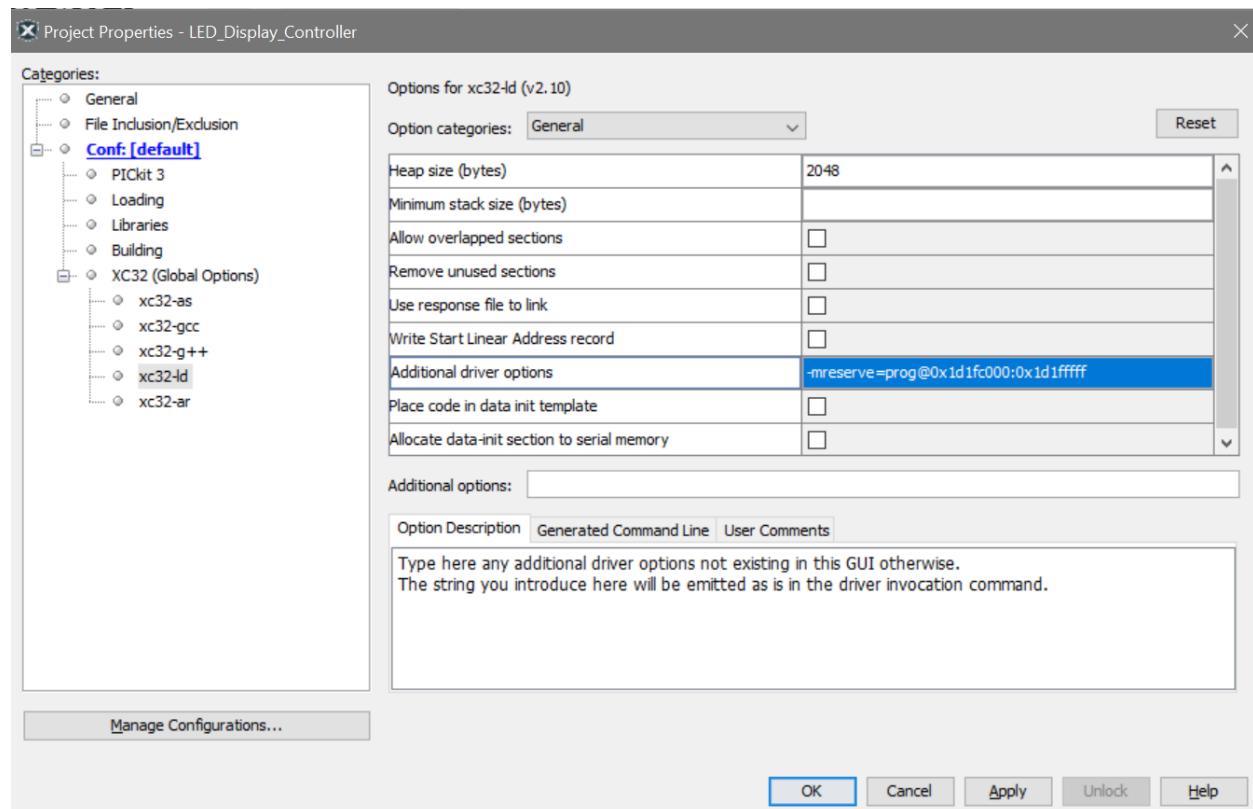

Acrylic Panel Corner Brackets:

Custom cut acrylic corner brackets hold the interior corners of the LED panels together. They are fixed to the LED panels with M3.5 Screws, which thread through the acrylic brackets into the same brass inserts in the LED panels which the T slotted frame is fixed to.

Logic Board Microcontroller Firmware:

The microcontroller on the logic board was programmed using a PIC KIT 3 programmer from Microchip. PIC KIT 4 may work as well, but has not been tested. The project Git repository (including hardware design files and app and embedded software) is located at this URL at the time of writing: https://github.com/drewsum/Electronic_Display. Contact Drew Maatman at drewmaatman@gmail.com should any issues arise accessing the project Git repository. The microcontroller on the logic board is programmed with firmware located in the project repository at `/swf/embedded_firmware/U601_firmware/`. The microcontroller firmware was complied with Microchip's XC32 compiler, version 2.10, using the MPLAB X IDE, version 5.15. The microcontroller firmware was compiled at **optimization level two**. The command line argument `-O2` must be added to the XC32 command line driver arguments section of the project settings. Failure to do so will result in screen flickering. Optimization level two may or may not require a Microchip XC32 Pro compiler license. We purchased the Pro license for \$30 for a one month subscription when building the project.
Reprogram the microcontroller on the logic board at your own risk. This should be a last-ditch troubleshooting/repair attempt. A microcontroller firmware failure is very rare.

In addition to **optimization level 2**, the compiler must also be configured to have a **heap size of 2048 bytes**, and have **additional driver options set to `-mreserve=prog@0x1d1fc000:0x1d1ffff`** under the **XC32 linker options**. These additional compiler settings are shown below:
